

**NAME**

**mbm\_grdtiff** – Create an executable shellscript which will generate a TIFF image of gridded data in a GMT grd file.

**VERSION**

Version 5.0

**SYNOPSIS**

**mbm\_grdtiff** **-Ifile** [**-Amagnitude**[/azimuth/elevation] **-Gcolor\_mode** **-H** **-Kintensity\_file** **-Nnudge\_x/nudge\_y** **-Oroot** **-S**[color/shade] **-V** **-W**[color\_style[/palette[ncolors]] | cptfile] ]

**Additional Options:**

[**-Dflipcolor/flipshade** **-MGSscalefactor** **-MGW** **-Q** **-Rw/e/s/n** **-X** **-Y** **-Zmin/max**[/mode]]

**DESCRIPTION**

**mbm\_grdtiff** is a macro to generate a shellscript which, when executed, will use the program **mbgrdtiff** to generate a geographically located TIFF image of gridded data. The primary purpose of this macro is to allow the simple, semi-automated production of a nice looking image with a few command line arguments. Several styles of images can be generated, including color fill and shaded relief maps. The available options mirror a subset of the options in **mbm\_grdplot**, allowing users to easily generate equivalent Postscript plots and TIFF images of gridded data. The program **mbgrdtiff** recognizes the coordinate system used by **mbgrid** or **mbmosaic** to generate a grid file, and then embeds the projection and grid bounds information into the TIFF image in accordance with the GeoTIFF standard. A number of GIS software packages recognize the georeferencing information in GeoTIFF images. In particular, images generated by **mbgrdtiff** from grids created using **mbgrid** or **mbmosaic** can be loaded into the GRASS, ArcInfo, ArcView, and ArcGIS GIS packages as geographically located coverages. The **mbgrid** and **mbmosaic** manual pages each contain an appendix with a complete list of the projected coordinate systems that may be used in grid generation. Some software packages (e.g. Winfrog) do not recognize the embedded coordinate system information, and install require a parallel "world" file to specify the bounds and resolution. The **-MGW** option causes a world file to be generated with a ".tfw" suffix.

**SIMPLE DESCRIPTION OF BASIC OPTIONS**

- A** *magnitude*[/azimuth/elevation]  
 Sets the parameters which control the synthetic illumination of the gridded data (shaded relief). The value *magnitude* is an effective vertical exaggeration which modulates the intensity of the shading; typical values are in the 0.1 to 10 range. The value *azimuth* is the azimuth in degrees from north from which the data is illuminated. The value *elevation* is the elevation of the illumination in degrees from horizontal. Defaults: *magnitude* = 0.2; *azimuth* = 0.0; *elevation* = 30.0;
- C** *contour\_control*  
 If **-C** is given alone, it causes unannotated contours to be drawn using a contour interval calculated from the data. The user may also use *contour\_control* to specify the contour interval. See the

COMPLETE DESCRIPTION OF OPTIONS section below for a more complete discussion.

- D** *[flipcolor/flipshade]*  
Normally, the color or grayscale tables used for color maps run from cool colors (or dark grays) for low grid values to hot colors (or light grays) for high grid values. This option reverses the color table so that cool colors (dark grays) correspond to high values and hot colors (light grays) to low values. If **-D** is given alone, it applies to the color table used for color or gray fill plots, shaded or unshaded. If the plot is to be shaded, either by synthetic illumination (**-G2**) or using an intensity file (**-K** and **-G3** options), then setting *flipshade* = 1 will cause the shading convention to be reversed (e.g. high intensities overlaid as light shading). Using **-D0/1** will flip the shading convention but leave the default color convention.
- G** *color\_mode*  
Turns on color fill plot and sets the style of the plot.  
  - color\_mode* = 1: Color/gray fill.
  - color\_mode* = 2: Color/gray fill shaded by synthetic illumination.
  - color\_mode* = 3: Color/gray fill shaded by an intensity file. The **-K** option must be used to specify the intensity file.
  - color\_mode* = 4: Color/gray fill of slope magnitude.
  - color\_mode* = 5: Color/gray fill shaded by slope magnitude.
- H** This "help" flag cause the program to print out a description of its operation and then exit immediately.
- I** *grdfile*  
Sets the name of the gridded data file to be plotted. Alternatively, *grdfile* may be a list of grid files (one filename on each line) to be plotted together.
- K** *intensity\_file*  
Sets the name of the gridded data file containing intensity values to be used for shading the map. Alternatively, *grdfile* may be a list of grid files (one filename on each line) to be used together. If a list of file is supplied, the intensity files must conform in order to the data grid files they will shade.
- N** *nudge\_x/nudge\_y* Specifies positional offset in meters of the output geotiff image relative to the input grid or mosaic.
- O** *root*  
Sets the root used to construct the filename of the output shellscript (*root.cmd*) and names of files created when the shellscript is run. Normally the name of the input grid file or grid file list is used as the *root*.
- S** *[color/shade]*  
This option enables effective histogram equalization of the color and/or shading of the gridded data. The equalization is not achieved by changing the data values, but rather by constructing the color or shading tables so that the boundaries in the tables encompass equal fractions of the data-points. This serves to focus color or shading contrasts in value ranges corresponding to the bulk of the data values. If **-S** is given alone or with *color* = 1, it enables equalization of the color table used for color or gray fill plots, shaded or unshaded. If the plot is to be shaded, either by synthetic illumination (**-G2**) or using an intensity file (**-K** and **-G3** options), then setting *shade* = 1 will cause the shading to be equalized. Using **-S0/1** will equalize the shading without equalizing the color table.

- U** *orientation*  
Normally the orientation of the plot (portrait or landscape) is selected automatically so as to maximize the plot scale. The **-U** option allows the user to set the plot orientation. If *orientation* = 1, a portrait plot will be produced; if *orientation* = 2, a landscape plot will be produced.
- V** Causes **mbm\_grdtiff** to operate in "verbose" mode so that it outputs more information than usual.
- W** [*color\_style*[/*palette*[*ncolors*]] | *cptfile*]  
This option controls the color scheme used for color fill plots.

If *color\_style* = 1 [default], then the color scheme used will be a continuous grading of colors. If *color\_style* = 2, the color scheme will be a set of discrete color intervals. The color palette used is set using *palette*. Five palettes are available:

<i>palette</i> = 1:	Haxby colors [default]
<i>palette</i> = 2:	high Intensity colors
<i>palette</i> = 3:	low Intensity colors
<i>palette</i> = 4:	grayscale
<i>palette</i> = 5:	uniform grayscale

A complete description of the color palettes is given in the COMPLETE DESCRIPTION OF OPTIONS section below.

The *ncolors* parameter sets the number of color values used in plotting, whether the colors are represented in a continuous color scale or a stepped, discrete color scale [default is 11].

If the option argument is the path to an existing **GMT** color palette (CPT) file, then that CPT file and its color scheme will be used for the plot

## COMPLETE DESCRIPTION OF OPTIONS

- A** *magnitude*[/*azimuth*]  
Sets the parameters which control the synthetic illumination of the gridded data (shaded relief). The value *magnitude* is an effective vertical exaggeration which modulates the intensity of the shading; typical values are in the 0.1 to 0.5 range. The value *azimuth* is the azimuth from which the data is illuminated. Defaults: *magnitude* = 0.2; *azimuth* = 0.0;
- D** [*flipcolor*/flipshade]  
Normally, the color or grayscale tables used for color maps run from cool colors (or dark grays) for low grid values to hot colors (or light grays) for high grid values. This option reverses the color table so that cool colors (dark grays) correspond to high values and hot colors (light grays) to low values. If **-D** is given alone, it applies to the color table used for color or gray fill plots, shaded or unshaded. If the plot is to be shaded, either by synthetic illumination (**-G2**) or using an intensity file (**-K** and **-G3** options), then setting *flipshade* = 1 will cause the shading convention to be reversed (e.g. high intensities overlaid as light shading). Using **-D0/1** will flip the shading convention but leave the default color convention.
- G** *color\_mode*  
Turns on color fill plot and sets the style of the plot.
  - color\_mode* = 1: Color/gray fill.
  - color\_mode* = 2: Color/gray fill shaded by synthetic illumination.
  - color\_mode* = 3: Color/gray fill shaded by an intensity file. The **-K** option must be used to specify the intensity file.
  - color\_mode* = 4: Color/gray fill of slope magnitude.
  - color\_mode* = 5: Color/gray fill shaded by

slope magnitude.

See the **mbgrdtiff** and **grdimage** manual pages for information on shading with intensity files

- H** This "help" flag cause the program to print out a description of its operation and then exit immediately.
- I** *grdfile*  
Sets the name of the gridded data file to be plotted. The data must be in a form acceptable to **GMT** version 3 programs (see the **GMT** Cookbook & Technical Reference). Alternatively, *grdfile* may be a list of grid files (one filename on each line) to be plotted together. This is useful when data from a region is broken up into several grid files rather than a single very large grid file.
- K** *intensity\_file*  
Sets the name of the gridded data file containing intensity values to be used for shading the map. Alternatively, *grdfile* may be a list of grid files (one filename on each line) to be used together. If a list of files is supplied, the intensity files must conform in order to the list of data grid files they will shade.
- M** A series of "miscellaneous" options are provided which are given as **-M** followed by a two character identifier, followed by any other parameters associated with that option. The **-M** options may be strung together separated by colons, e.g. "-MGQ100:GU:CA200/10", which is equivalent to "-MGQ -MGU -MCA200/10".
- MGD** *gmtdef/value*  
Allows the user to set the **GMT** default values used as the plot is constructed. This command may be given repeatedly to set as many **GMT** defaults as required. For example, to set the basemap annotation font to Courier, use "-MGDANOT\_FONT/Courier".
- MGS** *scalefactor*  
The gridded data is multiplied by *scalefactor*. This option is most often used flip the sign of the data (*scalefactor* = -1). [Default no scaling]
- MGW**  
The **-MGW** option causes a "world" file to be generated parallel to the GeoTiff image with a ".tfw" suffix. Some software packages (e.g. Winfrog) do not recognize the coordinate information embedded in the GeoTiff file, and look for a world file.
- O** *root*  
Sets the root used to construct the filename of the output shellscript (*root.cmd*) and names of files created when the shellscript is run. Normally the name of the input grid file or grid file list is used as the *root*.
- Q** Normally, the output plot generation shellscript includes lines which execute the program **xv** to display the TIFF image on the screen. This option causes those lines to be commented out so that executing the shellscript produces a TIFF image but does not attempt to display it on the screen.
- R** *west/east/south/north*  
*west*, *east*, *south*, and *north* specify the Region of interest. To specify boundaries in degrees and minutes [and seconds], use the dd:mm[:ss] format. Append **r** if lower left and upper right map coordinates are given instead of wesn. You may ask for a larger *w/e/s/n* region to have more room between the image and the axes. A smaller region than specified in the *grdfile* will result in a subset of the grid [Default is region given by the *grdfile*].
- S** [*color/shade*]  
This option enables effective histogram equalization of the color and/or shading of the gridded data. The equalization is not achieved by changing the data values, but rather by constructing the color or shading tables so that the boundaries in the tables encompass equal fractions of the data-points. This serves to focus color or shading contrasts in value ranges corresponding to the bulk of the data values. If **-S** is given alone or with *color* = 1, it enables equalization of the color table used for color or gray fill plots, shaded or unshaded. If the plot is to be shaded, either by synthetic illumination (**-G2**) or using an intensity file (**-K** and **-G3** options), then setting *shade* = 1

will cause the shading to be equalized. Using **-S0/I** will equalize the shading without equalizing the color table.

- V** Causes **mbm\_grdtiff** to operate in "verbose" mode so that it outputs more information than usual.
- W** *[color\_style[/palette[ncolors]] | cptfile]*  
This option controls the color scheme used for color fill plots.

If *color\_style* = 1 [default], then the color scheme used will be a continuous grading of colors. If *color\_style* = 2, the color scheme will be a set of discrete color intervals. The color palette used is set using *palette*. Seven palettes are available:

```
palette = 1:    Haxby colors [default]
palette = 2:    high Intensity colors
palette = 3:    low Intensity colors
palette = 4:    grayscale
palette = 5:    uniform grayscale
palette = 6:    uniform black
palette = 7:    uniform white
```

The RGB definitions of the color palettes are:

#### color palette 1 – Haxby Color Table

```
red:  255 255 255 255 240 205 138 106  50  40  37
green: 255 186 161 189 236 255 236 235 190 127  57
blue:  255 133  68  87 121 162 174 255 255 251 175
```

#### color palette 2 – High Intensity Colors

```
red:  255 255 255 255 128  0  0  0  0 128 255
green:  0  64 128 255 255 255 255 128  0  0  0
blue:   0  0  0  0  0  0 255 255 255 255 255
```

#### color palette 3 – Low Intensity Colors

```
red:  200 194 179 141  90  0  0  0  0  90 141
green:  0  49  90 141 179 200 141  90  0  0  0
blue:   0  0  0  0  0  0 141 179 200 179 141
```

#### color palette 4 – Grayscale

```
red:  255 230 204 179 153 128 102  77  51  26  0
green: 255 230 204 179 153 128 102  77  51  26  0
blue:  255 230 204 179 153 128 102  77  51  26  0
```

#### color palette 5 – Uniform Grayscale

```
red:  128 128 128 128 128 128 128 128 128 128 128
green: 128 128 128 128 128 128 128 128 128 128 128
blue:  128 128 128 128 128 128 128 128 128 128 128
```

#### color palette 6 – Uniform Black

```
red:   0  0  0  0  0  0  0  0  0  0  0
green:  0  0  0  0  0  0  0  0  0  0  0
blue:   0  0  0  0  0  0  0  0  0  0  0
```

#### color palette 7 – Uniform White

```
red:  255 255 255 255 255 255 255 255 255 255 255
green: 255 255 255 255 255 255 255 255 255 255 255
blue:  255 255 255 255 255 255 255 255 255 255 255
```

The Haxby colors have been adapted from a palette developed by Dr. William Haxby of the Lamont-Doherty Earth Observatory; this palette is pleasing to the eye and well suited for shading. The high intensity colors describe linear paths through RGB space from red to blue to green to purple; because the colors are high intensity they are not well suited to shading. The low intensity colors are similar to the high intensity, but muted and thus well suited to shading. The grayscale palette runs linearly from white to black and is commonly used for plots of sidescan and amplitude data. The uniform grayscale is useful for non-color shaded relief plots.

The *ncolors* parameter sets the number of color values used in plotting, whether the colors are represented in a continuous color scale or a stepped, discrete color scale [default is 11].

If the option argument is the path to an existing **GMT** color palette (CPT) file, then that CPT file and its color scheme will be used for the plot

- X** Normally, **mbm\_grdtiff** creates an executable shellscript and then exits. This option will cause the shellscript to be executed in the background before **mbm\_grdtiff** exits.
- Y** Normally, **mbm\_grdplot** generates nicely rounded numbers for the boundaries of the color palette. Often, the resulting color bounds extend well outside the range of the gridded data. This option causes the minimum and maximum color boundaries to exactly conform to the minimum and maximum values of the grid, or, if the **-Z** option is used, the minimum and maximum values specified by the user.
- Z** *min/max[/mode]*  
This option overrides the minimum and maximum values of the gridded data, affecting the color palette and the contour interval if those parameters are not specified by the user. By default (i.e. *mode* is omitted or equal to 0), the macro selects the color palette bounds so that they encompass *min* and *max* while using nicely rounded numbers. If *mode* is omitted or equal to 0, then the color palette will end near *min* and *max* whether it is linear stretched or histogram equalized. If *mode* = 1, then the color stretching calculations will be done using *min* and *max*, but then the first and last values in the color palette will be set to the actual minimum and maximum values so that all the data are displayed.

## EXAMPLES

Suppose we have obtained two GRD files, one containing gridded bathymetry (testbath.grd) and the other mosaiced amplitude (testamp.grd). In order to generate a color fill TIFF image, we use the **-G1** option. Because the data has been gridded as bathymetry (positive down) rather than as topography (positive up), the default plot will have "hot" colors for deep regions and "cold" colors for shallow regions; this is the opposite of the convention we usually use. In order to fix the colors, we have to either rescale the data by multiplying the bathymetry by **-1** (accomplished with **-MGS-1**), or flip the color palette (accomplished with **-D**). We use the latter approach:

```
mbm_grdtiff -Itestbath.grd -G1 -D \
-V -Obath_fill
```

In order to generate a grayscale plot of the amplitude mosaic, we use **-G1** and **-W1/4**. We also use **-D** so that high amplitude amplitudes are shown as dark.

```
mbm_grdtiff -Itestamp.grd -G1 -D -W1/4 \
-V -Oamp_fill
```

Now consider generating a shaded relief view of the gridded bathymetry. We choose to illuminate the bathymetry from the northeast (azimuth of 45 degrees) and to use a shading magnitude of 0.4 (**-A0.4/45**). We also use the **-X** flag this so that the plot generation shellscript is executed immediately. Here is the command:

```
mbm_grdtiff -Itestbath.grd \
-G2 -A0.4/45 -D -X -V \
-Obath_shade
```

Now, consider generating a plot of the bathymetry overlaid with the mosaiced amplitude. The amplitude overlay is specified using the `-K` option. We want the colors for the bathymetry to be chosen without histogram equalization, but we also want histogram equalization to be applied to the amplitude data used for shading. To do this, we use `-S0/1`, where the first number (0) specifies no histogram equalization of the color scale and the second number (1) causes histogram equalization of the shading amplitude data to be implemented. In order to maintain the convention that high amplitude amplitudes are black, we flip both the color palette (as in the previous example) and the shading scale with `-D1/1`. We could also flip the shading by specifying a negative shading magnitude (`-A-0.4`).

```
mbm_grdtiff -Itestbath.grd \
-G3 -Ktestamp.grd \
-S0/1 -D1/1 -A0.4 -X -V \
-Obath_amp
```

As an example, the contents of the plotting shellscript "bath\_fill\_tiff.cmd" are:

```
#!/bin/csh -f
#
# Shellscript to create TIFF image of data in grd file
# Created by macro mbm_grdtiff
#
# This shellscript created by following command line:
# mbm_grdtiff -Itestbath.grd -G1 -D -V -Obath_fill
#
# Define shell variables used in this script:
set TIFF_FILE      = bath_fill.tif
set CPT_FILE       = bath_fill.cpt
set MAP_REGION     = -49.28/-49.13/12.05/12.2
#
# Save existing GMT defaults
