

NAME

mbm_xyplot – Create an executable shellscript which will generate a GMT plot of xy data.

VERSION

Version 5.0

SYNOPSIS

mbm_xyplot **-I**[filepars:]file [**-I**[filepars:]file **-G**fill **-H** **-O**root **-P**pagesize **-S**symbol/size **-U**orientation **-V** **-W**pen]

Additional Options:

[**-B**tickinfo **-J**projection[/scale / width] **-L**title[:xlabel:ylabel] **-M**misc **-Q** **-R**w/e/s/n **-X** **-Z**]

Miscellaneous Options:

[**-MG**dgmtdef/value **-MGL**scalebar **-MGT**x/y/size/angle/font/just/text **-MGU**[/dx/dy][label] **-MIE**resolution **-MIT**type]

DESCRIPTION

mbm_xyplot is a macro to generate a shellscript of GMT commands which, when executed, will generate a Postscript plot of xy data. Axes may be linear, log, or any of several geographic projections. Data may be plotted as symbols or lines. The plot will be scaled to fit on the specified page size or, if the scale is user defined, the page size will be chosen in accordance with the plot size. The primary purpose of this macro is to allow the simple, semi-automated production of nice looking plots with a few command line arguments.

By default **mbm_xyplot** expects the input data files to have values organized in columns separated by white space. However, users may optionally specify a non-white-space delimiter for each file. Input data files can have an arbitrary number of columns. When two or more columns exist the one may specify which two columns to plot (the first vs second is the default). In addition, users may optionally specify a single column to be plotted versus data-point-number.

The standard syntax with which one selects columns to plot may also be embedded into a larger Perl expression, which will be evaluated for each line of the data file. In this way, one may do on-the-fly mathematics or substring extractions as required. Indeed, one may specify most any Perl expression that when evaluated, will be a numeric result for plotting. For example, one can multiply the values in a column by a constant, add the values of two columns together or even extract latitude and longitude degrees and minutes in a file of NMEA strings and convert the results to decimal degrees for plotting. The macro uses the specified delimiter to extract the values from each column, evaluate the expressions, and then leaves the result in temporary data in files to be read by the plotting shellscript. The temporary files are deleted on execution of the shell script by default, but can optionally be retained for debugging purposes.

For users seeking more control over the plot appearance, a number of additional optional arguments are provided. Truly ambitious users may edit the plot shellscript to take advantage of GMT capabilities not supported by this macro.

The output plot generation shellscript includes lines that execute a program to display the Postscript image on the screen. The program used to display the Postscript can be set using **mbdefaults** or by setting the environment variable \$MB_PS_VIEWER (the environment variable overrides the **mbdefaults** setting). If a Postscript viewer is not explicitly defined by either method, then the user's default program for viewing Postscript is invoked. Invoking the plot generation shellscript with a **-N** command line argument suppresses the screen display of the plot. The **-MIE** and **-MIP** arguments cause the plot generation shellscript to render the Postscript map onto an image in the specified format.

The plot scripts generated by this macro will work with GMT version 5.0 and later, and are not compatible

with earlier versions of GMT.

SIMPLE DESCRIPTION OF BASIC OPTIONS

- G** *fill*
 Select filling of symbols for xy plotting. Set the shade (0-255) or color (r/g/b) [Default is no fill]. To reset no fill, use *fill* = "N". For polygons, you may optionally specify **-Gpicon_size/pattern**, where *pattern* gives the number of the image pattern (1-32) OR the name of a icon-format file. *icon_size* sets the unit size in inch. To invert black and white pixels, use **-GP** instead of **-Gp**. See **GMTs Cookbook & Technical Reference Appendix E** for information on individual patterns.
- H** This "help" flag cause the program to print out a description of its operation and then exit immediately.
- I** *[filepars:]xy_file*
 Specifies a file containing (x,y) pairs to be plotted as lines or symbols. Optional parameters precede the file name and consist of a list of flag-argument pairs, strung together with colons. These arguments may include the column delimiter, which columns to plot, line and symbol characteristics and a flag to specify when multiple data segments are embedded in a single file. The looks like the following:

-IDdelimiter:Ccolumnsexpression:Gcolor:Ssymbol:Wweight:M:xyfile

 Default parameters are whitespace [D(\s+)], column 1 vs column 2 [Cc[1]_c[2]], black lines without symbols [SN], [GN], [W1], and no multiple segments (omitted M flag).

 Please see the "Complete Description of Options" below for details.
- O** *root*
 Sets the root used to construct the filename of the output shellscript (*root.cmd*) and names of files created when the shellscript is run. Normally the name of the input grid file or grid file list is used as the *root*.
- P** *pagesize*
 This option sets the size of the page the plot will be centered on. If the user does not set the plot scale, the plot will be sized as large as will fit on the designated page. If the user sets the plot scale such that the plot will not fit on the designated page, a larger page will be used. The supported page sizes include ANSI A, B, C, D, E, F, and E1, as well as most metric page sizes. See the **COMPLETE DESCRIPTION OF OPTIONS** section below for a complete list of the supported page sizes. The default page size is A.

- S** *symbol/size*
Selects symbol to be used for plotting the next xy data file. Setting *symbol* = "N" causes line plotting. The list of available symbols is given in the COMPLETE DESCRIPTION OF OPTIONS section below.
- U** *orientation*
Normally the orientation of the plot (portrait or landscape) is selected automatically so as to maximize the plot scale. The **-U** option allows the user to set the plot orientation. If *orientation* = 1, a portrait plot will be produced; if *orientation* = 2, a landscape plot will be produced.
- V** Causes **mbm_grdplot** to operate in "verbose" mode so that it outputs more information than usual.
- W** *pen*
Set pen attributes for xy plotting. See chapter 4.12 in the GMT Technical reference for a discussion of GMT pen values. [Defaults: width = 1, color = 0/0/0, texture = solid].

COMPLETE DESCRIPTION OF OPTIONS

- B** *tickinfo*
Sets map boundary tickmark intervals. See the **psbasemap** manual page for details. By default the program chooses basemap annotations based on the map boundaries.
- G** *fill*
Select filling of symbols for xy plotting. Set the shade (0-255) or color (r/g/b) [Default is no fill]. To reset no fill, use *fill* = "N". For polygons, you may optionally specify **-Gpicon_size/pattern**, where *pattern* gives the number of the image pattern (1-32) OR the name of a icon-format file. *icon_size* sets the unit size in inch. To invert black and white pixels, use **-GP** instead of **-Gp**. See **GMTs Cookbook & Technical Reference Appendix E** for information on individual patterns.
- H** This "help" flag cause the program to print out a description of its operation and then exit immediately.
- I** *[filepars:]xy_file*

Specifies the files containing the data to be plotted, and for each file, a list of file parameters which are comprised of the rules used by **mbm_xyplot** to parse and manipulate the x and y values on the fly, as well as the line and symbol characters used for plotting the results.

The file parameters are an optional list of flags and their arguments concatenated and strung together with colons. A full specification has the following general syntax although individual flags and their arguments need not appear in any particular order as long as argument follows corresponding flag.:

-IDdelimiter:Ccolumnsexpression:Gcolor:Ssymbol:Wweight:M:xyfile

The delimiter may be any character string. The default delimiter is whitespace.

By default, **mbm_xyplot** uses the first column as the x value and the second column as the y value for the plot. However, the **C** flag and column expression allows the user to chose other columns to plot. The general syntax is

C *c[xcol]_c[ycol]*

where 'xcol' and 'ycol' designate the x and y columns respectively. Columns are numbered starting at '1' one the left most column in the file. In addition, either *c[]* expression may be replaced with a single '#' symbol to plot the other variable vs. line number. For example,

C *#_c[col]*

will plot the values in column 'ycol' vs their line number in the file.

Other valid Perl expressions may be substituted for either column expression as well. For example, to plot in kilometers, a file whose columns contain x and y coordinates in meters, one would specify

C *c[0]/1000_c[1]/1000*

The line and symbol characteristics are set using the **G**, **S**, and **W** options. For example, the command **-IG255/0/0:Sa/0.1:xy.dat** will plot the (x,y) data pairs in the file xy.dat as 0.1 inch diameter red stars. [Default is a solid black line]. See the psxy man page for more details.

When multiple data files are specified (with multiple **-I** statements, the last **G**, **S**, and **W** options specified are for subsequent files. In order to plot different files using different line or symbol characteristics, new sets of commands can be specified for each file.

Finally, note that there are two ways in which one may plot multiple data sets on the same plot. One may specify multiple sets of file arguments [i.e. **-I[filepars:]xy_file**], one for each file to be plotted. This allows the most flexibility, including different one-the-fly manipulations and colors for each xy series.

An alternative is to utilize the "multiple segments" feature of **psxy**. Specify the **M** flag in the file argument list to invoke this feature. A single file may then contain all the data, one series after the next, with lines containing a single ">" and nothing more to delineate breaks in data segments. This is the default break character for psxy, and currently the only break character supported by mbm_xyplot. For example **-IM:xy.dat** would plot multiple data series in the file xy.dat whose segments were separated as in the following snippet:

```
1.2 3
1.3 5
>
0 .1
0.1 .4
```

-J *projection[/scale /width]*

Selects the map projection. By default the map projection is Mercator and the plot scale is chosen to fit on the selected page size (see **-P** option). The user may specify a different projection to be used, in which case the plot scale is still automatically chosen to fit the page. The user may also specify both the projection and the plot scale. If the projection specifying character is upper case, a plot width rather than a plot scale is used. The scale values are specified in inch/degree or in 1:xxxxx ratios. Plot widths are specified in inches. If the user specifies a plot scale such that the plot will not fit on the default A size page, a appropriately larger page size will be chosen.

CYLINDRICAL PROJECTIONS:

- Jclon0/lat0/scale** (Cassini)
- Jmscale** (Mercator)
- Joalon0/lat0/azimuth/scale** (Oblique Mercator – point and azimuth)
- Joblon0/lat0/lon1/lat1/scale** (Oblique Mercator – two points)
- Joclon0/lat0/lonp/latp/scale** (Oblique Mercator – point and pole)
- Jqlon0/scale** (Equidistant Cylindrical Projection (Plate Carree))
- Jtlon0/scale** (TM – Transverse Mercator)

- Ju***zone/scale* (UTM – Universal Transverse Mercator)
- Jy***lon0/lats/scale* (Basic Cylindrical Projection)

AZIMUTHAL PROJECTIONS:

- Ja***lon0/lat0/scale* (Lambert).
- Je***lon0/lat0/scale* (Equidistant).
- Jg***lon0/lat0/scale* (Orthographic).
- Jslon0/lat0/scale (General Stereographic)**

CONIC PROJECTIONS:

- Jb***lon0/lat0/lat1/lat2/scale* (Albers)
- Jllon0/lat0/lat1/lat2/scale (Lambert)**

MISCELLANEOUS PROJECTIONS:

- Jh***lon0/scale* (Hammer)
- Ji***lon0/scale* (Sinusoidal)
- Jk***lon0/scale* (Eckert VI)
- Jn***lon0/scale* (Robinson)
- Jr***lon0/scale* (Winkel Tripel)
- Jw***lon0/scale* (Mollweide)

NON-GEOGRAPHICAL PROJECTIONS:

- Jp***scale* (Linear projection for polar (theta,r) coordinates)
 - Jxx***-scale*[**lppow**][*y-scale*[**lppow**]] (Linear, log, and power scaling)
- More details can be found in the **psbasemap** manpages.

- L** *title[:xlabel[:ylabel]]*
Sets the title and the labels for the x and y axes of the plot. Note that a colon (:) rather than a slash (/) is used to separate the labels. Colons cannot be used in the labels themselves. If this option is not used, then a default title and colorscale label are provided. If the title is supplied alone, no x or y-axis labels will be provided.
- M** A series of "miscellaneous" options are provided which are given as –**M** followed by a two character identifier, followed by any other parameters associated with that option. The –**M** options may be strung together separated by colons, e.g. "-MGQ100:GU:CA200/10", which is equivalent to "-MGQ –MGU –MCA200/10".
- MGD** *gmtdef/value*
Allows the user to set the **GMT** default values used as the plot is constructed. This command may be given repeatedly to set as many **GMT** defaults as required. For example, to set the basemap annotation font to Courier, use "-MGDANOT_FONT/Courier".
- MGL** *scalebar*
Draws a simple map scale specified by the arguments in *scalebar*. The syntax used for the *scalebar* command by the **GMT** module **psbasemap** has changed over time; use the syntax appropriate for the **GMT** version you have installed. As of March 2017, the current **GMT** version is 5.3.2, and the scalebar arguments are described in the **psbasemap** manual page as:
[*g*][*j*][*J*][*n*][*x*]*refpoint*+*c*[*slon*]/*slat*+*wlength*[*e*][*f*][*k*][*M*][*n*][*u*][+*aalign*][+*f*][+*jjustify*][+*l*[*label*]][+*odx*]/*dy*][+*u*]
Draws a simple map scale centered on the reference point specified using one of four coordinate systems: (1) Use -Lg for map (user) coordinates, (2) use -Lj or -LJ for setting refpoint via a 2-char justification code that refers to the (invisible) map domain rectangle, (3) use -Ln for normalized (0-1) coordinates, or (4) use -Lx for plot coordinates (inches, cm, etc.). Scale is calculated for

latitude slat (optionally supply longitude slon for oblique projections [Default is central meridian]), length is in km, or append unit from e|f|k|M|n|u. Change the label alignment with +align (choose among l(ef), r(ight), t(op), and b(ottom)). Append +f to get a fancy scale [Default is plain]. By default, the anchor point on the map scale is assumed to be the center of the scale (MC), but this can be changed by appending +j followed by a 2-char justification code justify (see pstext for list and explanation of codes). Append +l to select the default label, which equals the distance unit (meter, foot, km, mile, nautical mile, US survey foot) and is justified on top of the scale [t]. Change this by giving your own label (append +llabel). Add +o to offset the map scale by dx/dy away from the refpoint in the direction implied by justify (or the direction implied by -Dj or -DJ). Select +u to append the unit to all distance annotations along the scale (for the plain scale, +u will instead select the unit to be appended to the distance length). Note: Use FONT_LABEL to change the label font and FONT_ANNOT_PRIMARY to change the annotation font. The height of the map scale is controlled by MAP_SCALE_HEIGHT, and the pen thickness is set by MAP_TICK_PEN_PRIMARY.

-MGT *x/y/size/angle/font/just/text*

Causes a text label to plotted on the map. *size* is text size in points, *angle* is measured in degrees counter-clockwise from horizontal, *fontno* sets the font type, *justify* sets the alignment. If *fontno* starts with a leading hyphen, then the remainder of *fontno* is taken to be a textstring with the desired fontname. See the **gmtdefaults** man page for names and numbers of available fonts (or run **psstext -L**). The alignment number refers to the part of the textstring that will be mapped onto the (x,y) point: 1 = Lower Left corner, 2 = Lower Center, 3 = Lower Right, 5 = Mid Left, 6 = Mid Center, 7 = Mid Right, 9 = Upper Left, 10 = Upper Center, 11 = Upper Right. This option may be given as many times as needed.

-MGU *[/dx/dy/][label]*

Draw Unix System time stamp on plot. User may specify where the lower left corner of the stamp should fall on the page relative to lower left corner of plot in inch [Default is (-0.75,-0.75)]. Optionally, append a label, or **c** (which will plot the command string.)

-MIE *resolution*

This option turns on rendering the Postscript map onto an output raster image and sets the image resolution to be *resolution* dots per inch.

-MIT *type*

This option turns on rendering the Postscript map onto an output raster image and sets the image type to be BMP (**-MITb**), EPS (**-MITe**), EPS with PageSize command (**-MITe**), PDF (**-MITf**), multi-page PDF (**-MITF**), JPEG (**-MITj**), PNG (**-MITg**), transparent PNG (**-MITG**), PPM (**-MITm**), SVG (**-MITs**, or TIFF (**-MITt**). The default image format is JPEG.

-O *root*

Sets the root used to construct the filename of the output shellscript (*root.cmd*) and names of files created when the shellscript is run. Normally the name of the input grid file or grid file list is used as the *root*.

-P *pagesize*

This option sets the size of the page the plot will be centered on. If the user does not set the plot scale, the plot will be sized as large as will fit on the designated page. If the user sets the plot scale such that the plot will not fit on the designated page, a larger page will be used. The supported page sizes are:

American ANSI sizes:

- A 8.5 x 11.0 in. (215.9 x 279.4 mm)
- B 11.0 x 17.0 in. (279.4 x 431.8 mm)
- C 17.0 x 22.0 in. (431.8 x 558.8 mm)
- D 22.0 x 34.0 in. (558.8 x 863.6 mm)
- E 34.0 x 44.0 in. (863.6 x 1117.6 mm)
- F 28.0 x 40.0 in. (711.2 x 1016.0 mm)

E1 44.0 x 68.0 in. (1117.6 x 1727.2 mm)

Metric ISO A sizes:

A0 841.0 x 1189.0 mm (33.11 x 46.81 in.)
 A1 594.0 x 841.0 mm (23.39 x 33.11 in.)
 A2 420.0 x 594.0 mm (16.54 x 23.39 in.)
 A3 297.0 x 420.0 mm (11.69 x 16.54 in.)
 A4 210.0 x 297.0 mm (8.27 x 11.69 in.)
 A5 148.0 x 210.0 mm (5.83 x 8.27 in.)
 A6 105.0 x 148.0 mm (4.13 x 5.83 in.)
 A7 74.0 x 105.0 mm (2.91 x 4.13 in.)
 A8 52.0 x 74.0 mm (2.05 x 2.91 in.)
 A9 37.0 x 52.0 mm (1.46 x 2.05 in.)
 A10 26.0 x 37.0 mm (1.02 x 1.46 in.)

Metric ISO B sizes:

B0 1000.0 x 1414.0 mm (39.37 x 55.67 in.)
 B1 707.0 x 1000.0 mm (27.83 x 39.37 in.)
 B2 500.0 x 707.0 mm (19.68 x 27.83 in.)
 B3 353.0 x 500.0 mm (13.90 x 19.68 in.)
 B4 250.0 x 353.0 mm (9.84 x 13.90 in.)
 B5 176.0 x 250.0 mm (6.93 x 9.84 in.)
 B6 125.0 x 176.0 mm (4.92 x 6.93 in.)
 B7 88.0 x 125.0 mm (3.46 x 4.92 in.)
 B8 62.0 x 88.0 mm (2.44 x 3.46 in.)
 B9 44.0 x 62.0 mm (1.73 x 2.44 in.)
 B10 31.0 x 44.0 mm (1.22 x 1.73 in.)

Metric ISO C sizes:

C0 914.4 x 1300.5 mm (36.00 x 51.20 in.)
 C1 650.2 x 914.4 mm (25.60 x 36.00 in.)
 C2 457.2 x 650.2 mm (18.00 x 25.60 in.)
 C3 325.1 x 457.2 mm (12.80 x 18.00 in.)
 C4 228.6 x 325.1 mm (9.00 x 12.80 in.)
 C5 162.6 x 228.6 mm (6.40 x 9.00 in.)
 C6 114.3 x 162.6 mm (4.50 x 6.40 in.)
 C7 81.3 x 114.3 mm (3.20 x 4.50 in.)

MB-System large format sizes:

m1 1371.6 x 1828.8 mm (54.00 x 72.00 in.)
 m2 1371.6 x 2133.6 mm (54.00 x 84.00 in.)
 m3 1371.6 x 2438.4 mm (54.00 x 96.00 in.)
 m4 1524.0 x 1828.8 mm (60.00 x 72.00 in.)
 m5 1524.0 x 2133.6 mm (60.00 x 84.00 in.)
 m6 1524.0 x 2438.4 mm (60.00 x 96.00 in.)

The default page size is A.

- Q** Normally, the output plot generation shellsript includes lines which execute a program to display the Postscript image on the screen. This option causes those lines to be commented out so that executing the shellsript produces a Postscript plot but does not attempt to display it on the screen. Alternatively, invoking the plot generation shellsript with a **-N** command line argument also suppresses the screen display of the plot. The program to be used to display the Postscript is set using **mbdefaults**; the default value can be overridden by setting the environment variable **\$MB_PS_VIEWER**.

- R** *west/east/south/north*
west, *east*, *south*, and *north* specify the Region of interest. To specify boundaries in degrees and minutes [and seconds], use the dd:mm[:ss] format. Append **r** if lower left and upper right map coordinates are given instead of wesn. You may ask for a larger *w/e/s/n* region to have more room between the image and the axes. A smaller region than specified in the grdf file will result in a subset of the grid [Default is region given by the grdf file].
- S** *symbol/size*
Selects symbol to be used for plotting the next xy data file. Setting *symbol* = "N" causes line plotting. Choose between:
- Sa** **star**. *size* is radius of circumscribing circle.
- Sb** **bar** extending from *base* to *y*. *size* is bar width. By default, *base* = 0. Append */base* to change this value. Append **u** if *size* is in x-units [Default is inch].
- Sc** **circle**. *size* is diameter of circle.
- Sd** **diamond**. *size* is side of diamond.
- Se** **ellipse**. Direction (in degrees counterclockwise from horizontal), *major_axis* (in inch), and *minor_axis* (in inch) must be found in columns 3, 4, and 5.
- Sf** **fault**. Give distance gap between ticks and ticklength in inch. If gap is negative, it is interpreted to mean number of ticks instead. Append **l** or **r** to draw tick on the left or right side of line [Default is centered]. Upper case **L** or **R** draws a triangle instead of line segment.
- Sh** **hexagon**. Give side in inch.
- Si** **inverted triangle**. Give side in inch.
- Sl** **letter** or text string. Give size in inch, and append */string* after the size. Note that the size is only approximate; no individual scaling is done for different characters. Remember to escape special characters like *.
- Sp** **point**. No size needs to be specified (1 pixel is used).
- Ss** **square**. Give side in inch.
- St** **triangle**. Give side in inch.
- Sv** **vector**. Direction (in degrees counterclockwise from horizontal) and length (in inch) must be found in columns 3 and 4. *size*, if present, will be interpreted as arrow width/headlength/headwidth (in inch) [Default is 0.03/0.12/0.1 inch]. By default arrow attributes remains invariant to the length of the arrow. To have the size of the vector scale down with decreasing size, append *nnorm*, where vectors shorter than *norm* will have their attributes scaled by *length/norm*.
- SV** Same as **-Sv**, except azimuth (in degrees east of north) should be given instead of direction. The azimuth will be mapped into an angle based on the chosen map projection (**-Sv** leaves the directions unchanged.)
- Sx** **cross**. Give length in inch.
- U** *orientation*
Normally the orientation of the plot (portrait or landscape) is selected automatically so as to maximize the plot scale. The **-U** option allows the user to set the plot orientation. If *orientation* = 1, a portrait plot will be produced; if *orientation* = 2, a landscape plot will be produced.
- V** Causes **mbm_xyplot** to operate in "verbose" mode so that it outputs more information than usual.
- W** *pen*
Set pen attributes for xy plotting. See chapter 4.12 in the GMT Technical reference for a discussion of GMT pen values. [Defaults: width = 1, color = 0/0/0, texture = solid].

- X** Normally, **mbm_xyplot** creates an executable shellscript and then exits. This option will cause the shellscript to be executed in the background before **mbm_xyplot** exits.
- Z** **mbm_xyplot** extracts the desired columns of the input data and creates secondary files with the xy values to be plotted. Normally these files are left in place by the plot shellscript to be used multiple times. The **-Z** option causes the shellscript to delete those secondary files.

EXAMPLES

Suppose we have obtained a swath sonar data file called sb2112_example.mb41 collected using a SeaBeam 2112 sonar. In order to obtain an xy plot of the center beam depth versus time, we first extract the time-depth xy doubles from the swath sonar file using **mblist**:

```
mblist -F41 -Isb2112_example.mb41 -OmZ > mz.dat
```

Here time is in seconds from the start of the file and the depths are in meters, positive upward (topography rather than bathymetry). Now, we use **mbm_xyplot** to generate shellscripts which in turn generate plots when executed. First, we generate a simple black line plot:

```
mbm_xyplot -Imz.dat -Omz
```

The above command generates an executable shellscript mz_line.cmd; executing this shellscript will generate a Postscript plot and display it on the screen.

Suppose we also have a sparse set of depth estimates in a file called sr.dat obtained by picking the seafloor on a seismic reflection record, and we wish to compare the two sets of depths. We can plot the swath sonar derived depths as a black line and the seismic derived depths as red stars as follows:

```
mbm_xyplot -Omz_sr -Imz.dat \
-IG255/0/0:Sa/0.1:sr.dat
```

As an example, the contents of the plotting shellscript "mz.cmd" are:

```
#
# Shellscript to create Postscript plot of data in grd file
# Created by macro mbm_xyplot
#
# This shellscript created by following command line:
# mbm_xyplot -Imz.dat -Omz
#
# Save existing GMT defaults
echo Saving GMT defaults...
gmtdefaults -L > gmtdefaults$$
#
# Set new GMT defaults
echo Setting new GMT defaults...
gmtset ANOT_FONT Helvetica
gmtset LABEL_FONT Helvetica
gmtset HEADER_FONT Helvetica
gmtset ANOT_FONT_SIZE 8
gmtset LABEL_FONT_SIZE 8
gmtset HEADER_FONT_SIZE 10
gmtset FRAME_WIDTH 0.07499999999999997
gmtset TICK_LENGTH 0.07499999999999997
gmtset PAGE_ORIENTATION LANDSCAPE
gmtset COLOR_BACKGROUND 0/0/0

ADVANCED EXAMPLES

Suppose we have a file of NMEA GGA strings logged from a GPS receiver whose data looks like the following:

filename: gps.raw:

```

$GPGGA,23.0,5427.89080,N,14600.29458,W,1,10,0.9,19.01,M,6.40,M,,*70
$GPGGA,24.0,5427.89248,N,14600.30088,W,1,10,0.9,19.39,M,6.40,M,,*7B
$GPGGA,25.0,5427.89424,N,14600.30713,W,1,10,0.9,19.72,M,6.40,M,,*7C

```

We can specify a comma delimited file and convert the latitude and longitude fields to decimal degrees on the fly with the following:

```

mbm_xyplot -ID,:C'substr(c[5],0,3)+substr(c[5],3,length(c[5])) /60_substr(c[3],0,2)+sub-
str(c[3],2,length(c[3]))/60':gps.raw

```

This is about as ugly as it gets. However, it is quite straightforward and very handy, so let us pick this apart. The `-I` flag specifies the file to plot and its parameters. The `D` subfield followed by `'` indicates the file is comma delimited. The `C` subfield followed by the Perl expression extracts fields to plot. There are two expressions here, the `x` values, (longitude) and the `y` values (latitude) separated by an `"_"`. In the longitude expression, the degree portion of the longitude, which is the 5th field (`c[5]`) is extracted and added to the minute portion of the longitude divided by 60. The same is done with the latitude field, (`c[3]`).

Note the single quotes surrounding the C expression. These are required to ensure complex expressions such as these are not inadvertently interpreted by the shell.
